

# ABSTRACT

Provides a game processing apparatus capable of getting players more excited about playing games.

For that reason, the game processing apparatus of the present invention processes games on the basis of players' operating signals, and is equipped with processing circuits (10), which process the above-mentioned games on the basis of operating signals supplied from input devices (2b) operated by the players, and which generate the image data for these games. When an operating signal equivalent to a player's victory declaration is input from an input device (2b), the processing circuits (10) process subsequent operating signals input by the player as invalid signals until a prescribed condition is achieved.
